

# Motion Planning and Control in FRC

Jared Russell  
Tom Bottiglieri  
Austin Schuh

# Why are we here?

Robots should move  
less like this

And more like this

# Why are we here?

- **Control systems are fun**
- **Software is where most of the hard problems in robotics are**
  - Many of the techniques discussed today are common in industry
- **Motion control makes your FRC robot better!**
- *Motivating examples...*

# Go from here to there...

# Coordinated motion...

254

# Vision-driven targeting...

254

# How can we do it?

## Dead reckoning

(represents  
actual state of  
robot)

(represents  
desired state of  
robot)

10 Feet

Distance = 10 feet  
Full Speed = 5 ft/sec

$10 \text{ feet} / 5 \text{ (ft / sec)} = 2.0 \text{ seconds}$

*Just drive at full speed for 2.0 seconds and we'll be at the goal!*

# Let's try using a sensor!

Dead reckoning  
Bang-bang

```
while (true) {  
    error = goal_distance - current_distance  
    if (error > 0) {  
        Drive(1.0);  
    } else if (error < 0) {  
        Drive(-1.0);  
    } else {  
        Drive(0.0);  
    }  
}
```

***What is wrong with this code?***

# Slow down near the goal...

Dead reckoning  
Bang-bang  
PID

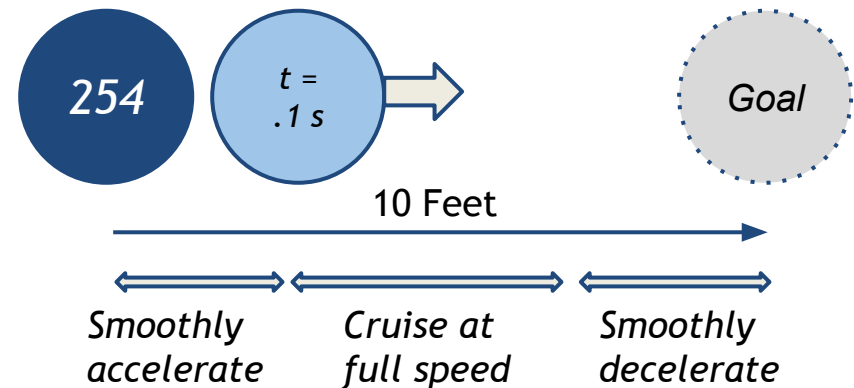

$$u(t) = \underbrace{K_p e(t)}_{\text{Proportional}} + \underbrace{K_i \int_0^t e(\tau) d\tau}_{\text{Integral}} + \underbrace{K_d \frac{d}{dt} e(t)}_{\text{Derivative}}$$

*Slow down near the goal*      *Overcome friction*      *Add damping*

# Take it one step further...

(represents desired  
intermediate state of robot)

Dead reckoning  
Bang-bang  
PID  
Motion profiles

***A well-planned  
profile makes  
precise control  
easier!***

# Some quick definitions...

## Paths and Trajectories

# Some quick definitions...

## Paths and Trajectories Motion Profile

# Some quick definitions...

Paths and Trajectories

Motion Profile

Feedforward and Feedback

**Desired State of Motion**

*at time  $t = .1$  s along the trajectory*

**Feedforward**

*at time  $t = .1$  s, I should be going this fast*

**Feedback**

*at time  $t = .1$  s, I should be there, but I am actually here, so I should go (faster/slower)*

# Some quick definitions...

Paths and Trajectories

Motion Profile

Feedforward and Feedback

**Forward and Inverse Kinematics**

## **Forward Kinematics**

*Joint space → Configuration space*

“My left wheel went forward 2 inches, my right wheel went forward 4 inches” → I went forward while turning counter-clockwise

## **Inverse Kinematics**

*Configuration space → Joint space*

“I want to turn clockwise 90 degrees”  
→ Left wheel must go forward for X inches, Right wheel must go backward for X inches

# The Motion Control Process

1. Figure out where you want to go
2. Find a path
3. Find a trajectory
4. Follow the trajectory
  - a. Figure out where you should be right now
  - b. Feedforward control +
  - c. Feedback control

*Doing these sequentially is often simpler than doing them simultaneously*

# Path Planning

- What is the sequence of configurations the mechanism will move through between start and goal?
- The 1D case is usually trivial
- ...but the 2D (or more) case is interesting

# Simple Path Planning

- Connect the dots - lots of ways to do it!
- Curve fitting
  - Cubic splines
  - Quintic splines
- Caveats
  - Loops
  - Overfitting
- Spline fit code:
  - [Team 254](#)
  - [Team 236](#)

*Hermite Specification*

# 2D (Hermite) cubic spline fit

## Inputs:

Start (x, y) at  $s = 0$

End (x, y) at  $s = 1$

4 unknowns, 4 equations

**Solve!**

## Equations:

$$x(s) = A_x s^3 + B_x s^2 + C_x s + D_x$$

$$y(s) = A_y s^3 + B_y s^2 + C_y s + D_y$$

$$dx/ds(s) = 3A_x s^2 + 2B_x s + C_x$$

$$dy/ds(s) = 3A_y s^2 + 2B_y s + C_y$$

If you care about heading, you can choose these such that  $\text{atan2}(dy/ds(s), dx/ds(s)) = \text{heading}$

# Advanced Path Planning

- Active area of research in academia
- Applications in robotics, video games, optimization and routing, etc.

# Trajectory Generation

- Ok, so we have a path. How fast should we traverse it? How do we:
  - Move to the goal as quickly as possible?
  - Obey constraints on maximum velocity, acceleration, (jerk)?
  - Know precisely where (and how fast) the mechanism should be moving at all points in time?
  - *Here is one such approach...*

# Polynomial method for triangular or trapezoidal velocity profiles

- Remember your kinematics:

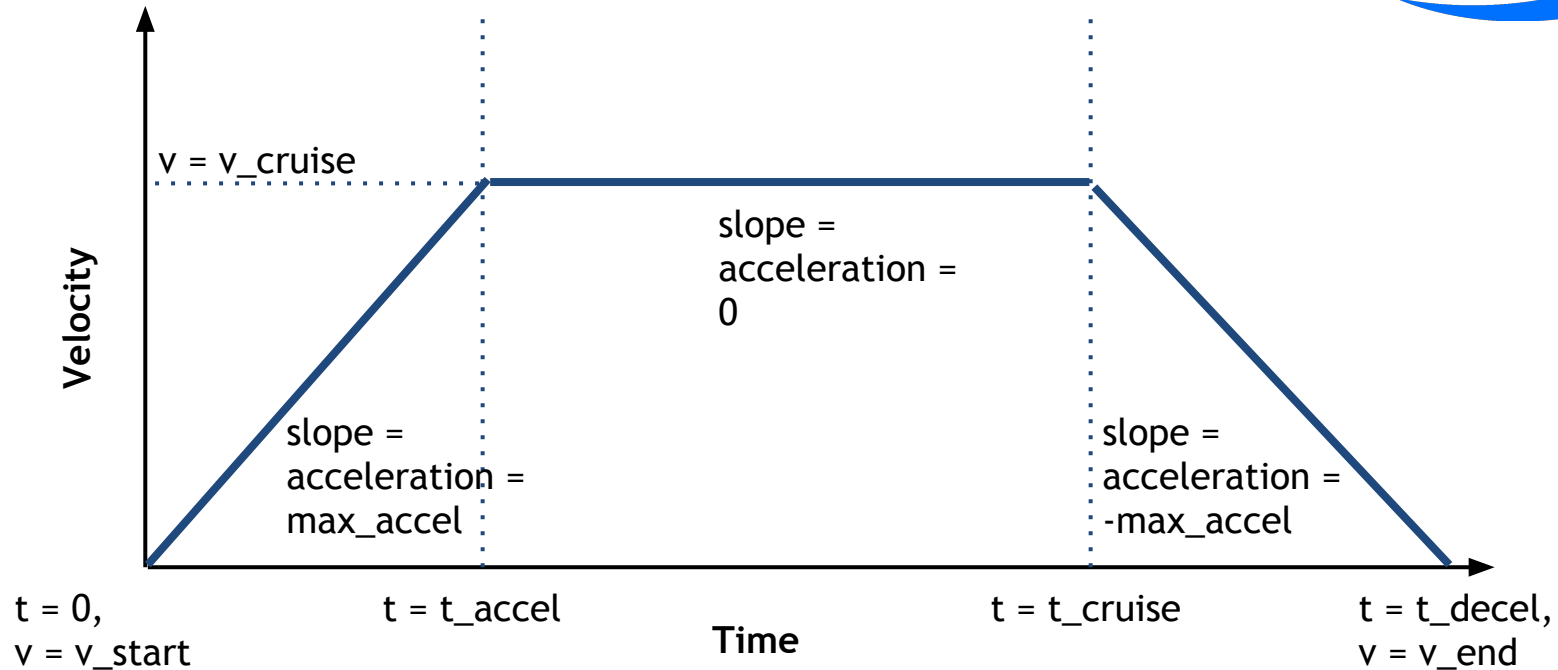

(1)  $v_f = v_i + a t$

(2)  $x_f = x_i + v t + \frac{1}{2} a t^2$

(3)  $x_f = x_i + t (v_i + v_f) / 2$

(4)  $v_f^2 = v_i^2 + 2 a (x_f - x_i)$

- There are up to three piecewise segments of motion in the motion (acceleration, cruise, deceleration)

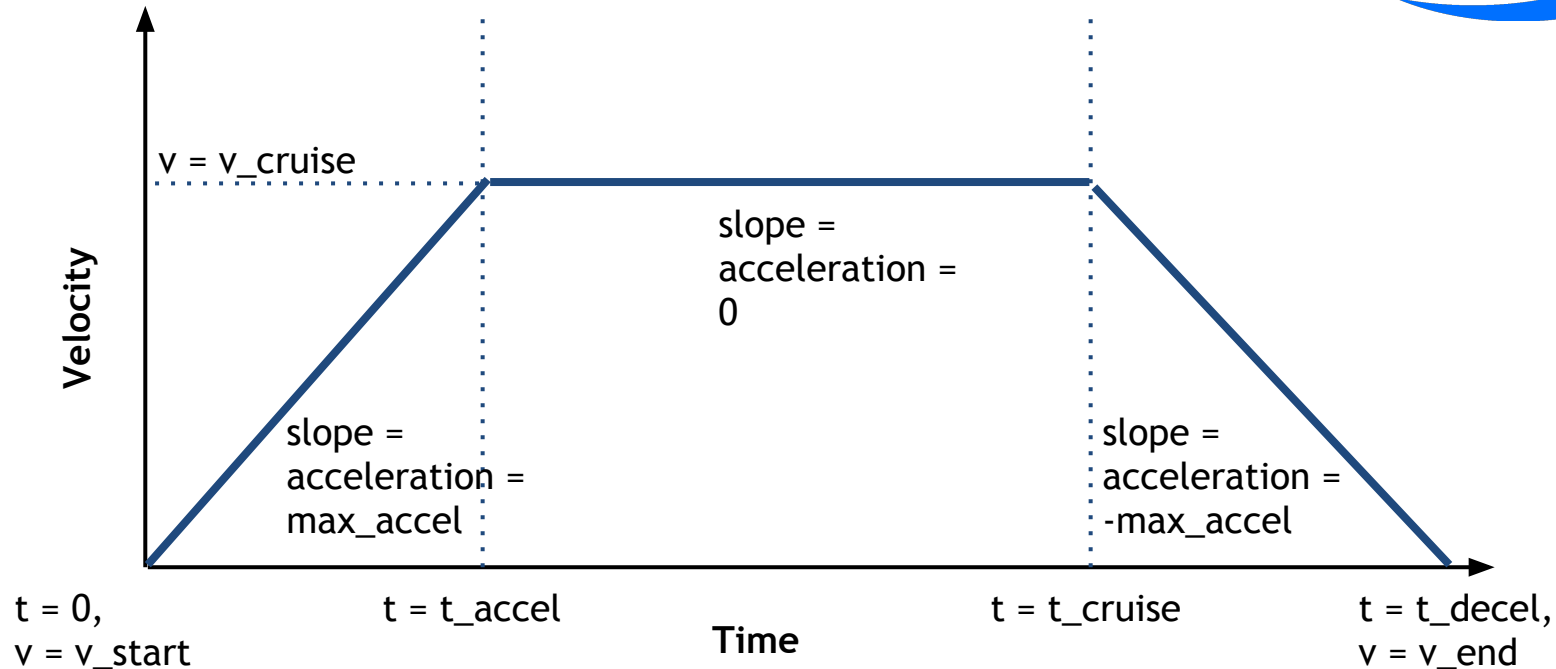

- First step: Find the cruising velocity  $v_{\text{cruise}}$

- First step: Find the cruising velocity  $v_{\text{cruise}}$ 
  - Pretend there is no velocity limit: How fast could we go? (hint: distance to accel to  $v_{\text{cruise}}$  plus distance to decel to  $v_{\text{end}}$  must equal total distance)
  - $v_{\text{cruise}} = \text{Min}(\text{max\_velocity}, v_{\text{cruise}})$

- Next:

- figure out how much distance you will cover to accelerate from  $v_{\text{start}}$  to  $v_{\text{cruise}}$  (hint:  $x_f = x_i + v t + \frac{1}{2} a t^2$ )
- ...and the same to decelerate from  $v_{\text{cruise}}$  to  $v_{\text{end}}$

- Finally:

- How long are you at cruise velocity?
- Total distance = distance during accel + distance during decel + distance during cruise
- Notice that cruise distance is zero in the case of a triangular profile

# The Result

- We now have a function where we can lookup the desired position, velocity, and acceleration of the system for a given time  $t$  since the beginning of the motion

# Alternative Approaches

- **Boxcar Filter Method**
  - Inspired by signal processing
  - Use a chain of integrators to model rate constraints
  - Pros:
    - Fast, Doesn't require floating point math
    - Can deal with limited jerk, snap, etc.
  - Cons:
    - Cannot deal with constraints that change over time
    - Only work for 1D problems
  - This is how the Talon SRX does its motion profiling
  - More information in [this Chief Delphi thread](#)

But that is a 1D trajectory...  
...what about 2D+?

- One simple approach:
  - At time  $t$ , figure out the current distance the robot should have covered
  - Figure out the arc length of the spline corresponding to this distance

$$L = \int_{\alpha}^{\beta} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$$

# Non-constant Constraints

- A tank drive robot has coupled constraints
  - Can only translate so fast depending on curvature of path (because the outside wheel is the limiting factor)
  - $v = (\text{left\_wheel\_velocity} + \text{right\_wheel\_velocity}) / 2$
  - $w = (\text{right\_wheel\_velocity} - \text{left\_wheel\_velocity}) / \text{width\_of\_wheelbase}$

- **Solution (Numerical Integration Approach):**
  - Rather than computing switching times, divide the path up into discrete samples
  - For each sample, compute the maximum velocity based on curvature or other constraints

- Next, starting at the beginning state, assign a velocity to each point that is  $\text{Min}(\text{max\_velocity}, \text{max\_reachable\_velocity})$

- One last step: Do the same thing *from end to beginning*

# The Motion Control Process

1. Figure out where you want to go
2. Find a path
3. Find a trajectory
4. **Follow the trajectory**
  - a. Figure out where you should be right now
  - b. Feedforward control +
  - c. Feedback control

# Trajectory Following

## 1. Figure out where you should be right now

1D case is easy

```
setpoint = LookUpSetpoint(t)  
error = setpoint.pos - actual_position
```

2D navigation case

*Along-track, cross-track, and heading components to error*

# Feedforward

- Basic Idea
  - If you have information about your system, tell your controller!
  - Trajectories encode all the information necessary to tell a “perfect” robot to follow them exactly
  - The feedback part will take care of deviations from perfection

# Trajectory Following

## 2. Feedforward control

```
setpoint = LookUpSetpoint(t)  
SetMotorSpeed(Kv * setpoint.vel)
```

*“Kv” is a velocity constant, representing a unit conversion between real-world velocities and motor speeds*

Ex. a robot drive is measured to move at 10 ft/sec at full power  
The resulting Kv is then 0.1 (so that a velocity setpoint of 1.0 results in full power)

# Trajectory Following

## 2. (Better) Feedforward control

```
setpoint = LookUpSetpoint(t)
SetMotorSpeed(Kv * setpoint.vel +
              Ka * setpoint.acc)
```

*“Ka” is an acceleration constant, telling your controller to add a little extra power to accelerate, and a little less to decelerate.*

Easiest to tune by first tuning Kv, then experimenting with Ka.

# Trajectory Following

## 3. Feedback control

```
setpoint = LookUpSetpoint(t)
error = setpoint.pos - actual_position
error_deriv = (error - error_last) / dt
SetMotorSpeed(Kv * setpoint.vel +
              Ka * setpoint.acc +
              Kp * error +
              Kd * error_deriv)
error_last = error
```

***Integral usually isn't needed anymore,  
except sometimes at the very end***

NOTE: The slides as presented contained an error here; there is no need to subtract setpoint velocity in this formulation, since error\_last is relative to the old position setpoint.

These slides are now correct.

$$u(t) = \underbrace{K_p}_{\text{Proportional}} e(t) + \underbrace{K_i \int_0^t e(\tau) d\tau}_{\text{Integral}} + \underbrace{K_d \frac{d}{dt} e(t)}_{\text{Derivative}}$$

# Tuning: Feedforward first

- Run the system at full speed and record a plot of position vs. time
  - Record maximum velocity
  - Record maximum acceleration (slope)
  - $K_v = 1 / \text{maximum velocity}$
- Create a motion profile with only  $K_v$  (all other constants set to 0)
- Adjust  $K_a$  until you track reasonably well

# Tuning: Add the feedback

- Start with  $K_p$ ...it can be really high, because errors are so small thanks to feedforward (*we typically track drive or elevator trajectories within an inch or two*)
- The feedforward makes the response less sensitive to  $K_p$  than in a pure feedback setup
- Most of the time only  $K_p$  is needed
- Add  $K_d$  if you aren't satisfied with tracking
  - We only use  $K_d$  on turning loops because of how sensitive they are

# Best Practices

- Do the simplest thing possible!
- Mechanical robustness is important
- Visualization is key
- Good sensing makes everything easier
- Precise timing is important
- Linearity is important
- The Talon SRX can now do a lot of this for you!

# Timing

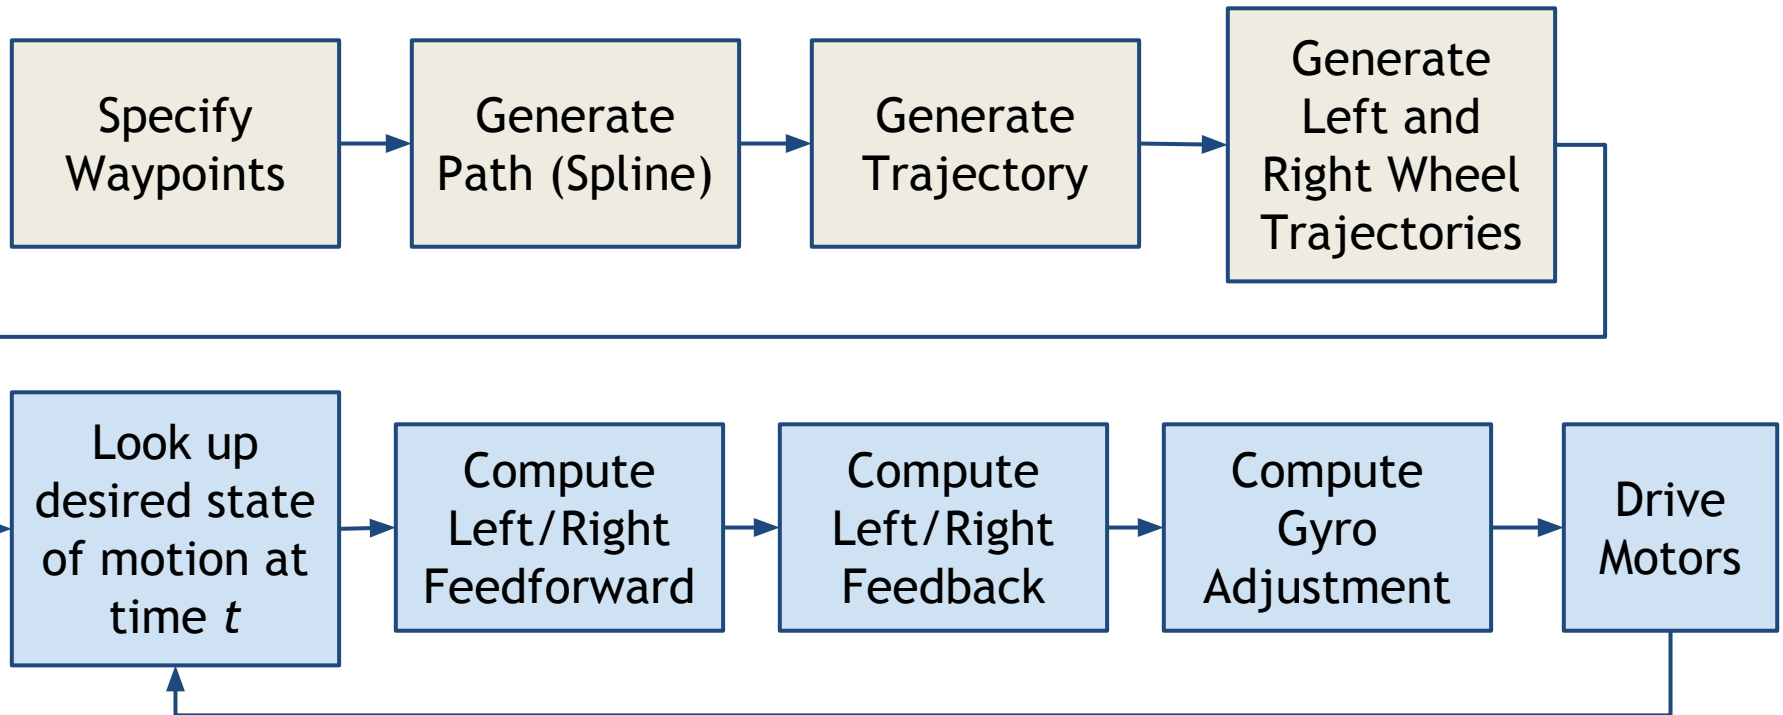

- We run all of our loops in their own thread at 200 Hz (you can give this thread real-time priority in C++ with some hackery)
  - Why 200 Hz?
- 2015 Java Timer code: Uses Thread.sleep()!
- Monitor CPU usage to make sure you aren't hitting 100% regularly
- **Always use a measured *dt*!**
  - getFPGATimestamp()

# Putting it All Together

## Simple Spline-following Drivetrain

*Gyro adjustment in this case is just a proportional controller on the desired heading*

# Putting it All Together

## Coordinated Motion

- Generate a separate trajectory for each rigid body
- Use the numerical integration approach to ensure that the trajectories stay synchronized
  - You can do this recursively in the control loop itself!

# Putting it All Together

## Vision-driven Position Control

- Cheap cameras make poor feedback signals
- Instead, use the camera to generate the goal position, and use separate sensors (gyro, encoders, potentiometer, etc.) to close the loop on position

# Questions?

Now get out there and move!
